

Weighted Low-rank Tensor Recovery for Hyperspectral Image Restoration

Yi Chang, Luxin Yan, Xi-Le Zhao, Houzhang Fang, Zhijun Zhang and Sheng Zhong

Abstract—Hyperspectral imaging, providing abundant spatial and spectral information simultaneously, has attracted a lot of interest in recent years. Unfortunately, due to the hardware limitations, the hyperspectral image (HSI) is vulnerable to various degradations, such as noises (random noise), blurs (Gaussian and uniform blur), and down-sampled (both spectral and spatial downsample), each corresponding to the HSI denoising, deblurring and super-resolution task, respectively. Previous HSI restoration methods are designed for one specific task only. Besides, most of them start from the 1-D vector or 2-D matrix models and cannot fully exploit the structurally spectral-spatial correlation in 3-D HSI. To overcome these limitations, in this work, we propose a unified low-rank tensor recovery model for comprehensive HSI restoration tasks, in which non-local similarity within spectral-spatial cubic and spectral correlation are simultaneously captured by 3-order tensors. Furthermore, to improve the capability and flexibility, we formulate it as a weighted low-rank tensor recovery (WLRTR) model by treating the singular values differently, and study its analytical solution. We also consider the stripe noise in HSI as the sparse error by extending WLRTR to robust principal component analysis (WLRTR-RPCA). Extensive experiments demonstrate the proposed WLRTR models consistently outperform state-of-the-art methods in typical HSI low-level vision tasks, including denoising, destriping, deblurring, and super-resolution.

Index Terms—Low-rank tensor approximation, higher-order singular value decomposition, hyperspectral image restoration.

I. INTRODUCTION

The hyperspectral image consists of multiple discrete bands at specific frequencies. The HSI can deliver additional information that the human eye fails to capture for real scenes, and has been attracting a lot of interest for researches from a wide range of application fields, such as anomaly detection [1] and classification [2]. However, HSI always suffers from various degradations, such as random noise (caused by photon effects), stripe noise (due to calibration error between adjacent detectors), blur (on account of atmospheric turbulence or system motion), and low spatial resolution (because of the hardware limitation). It is economically unsustainable and impractical

to improve the HSI quality merely by hardware scheme. Therefore, it is natural to introduce the image processing based approaches for obtaining a high-quality HSI before the subsequent applications. Mathematically, the problem of HSI restoration can be formulated by a linear model as follow:

$$\mathcal{Y} = \mathcal{T}_{sa}(\mathcal{X}) + \mathcal{E} + \mathcal{N}, \quad (1)$$

where $\mathcal{Y} \in \mathbb{R}^{r \times c \times B}$ is an observed low spatial-resolution image, $\mathcal{X} \in \mathbb{R}^{R \times C \times B}$ ($r \ll R, c \ll C$) represents the original high spatial-resolution image, $\mathcal{E} \in \mathbb{R}^{r \times c \times B}$ denotes the sparse error (mainly the stripe noise), $\mathcal{N} \in \mathbb{R}^{r \times c \times B}$ means the additive random noise, and $\mathcal{T}_{sa}(\bullet)$ stands for the spatially linear degradation operator.

With different settings, Eq. (1) can represent different HSI restoration problems. When $\mathcal{T}_{sa}(\bullet)$ is an identity tensor, the problem (1) becomes HSI denoising (only consider \mathcal{N}) or HSI destriping (only consider \mathcal{E}), or HSI mixed noise removal (both \mathcal{N} and \mathcal{E}); when $\mathcal{T}_{sa}(\bullet)$ is a blur operator, the problem (1) turns into the HSI deblurring; for HSI super-resolution, $\mathcal{T}_{sa}(\bullet)$ is a composite operator of blurring and spatial down-sampling. Moreover, in HSI super-resolution, there is another guided low spectral-resolution multispectral image $\mathcal{Z} \in \mathbb{R}^{R \times C \times b}$ ($b \ll B$) (usually RGB color image), which can be formulated as follow:

$$\mathcal{Z} = \mathcal{T}_{sc}(\mathcal{X}) + \mathcal{N}, \quad (2)$$

where $\mathcal{T}_{sc}(\bullet)$ denotes a spectral downsampling procedure, which can be expressed as $\mathcal{X} \times_3 \mathbf{P}$, and $\mathbf{P} \in \mathbb{R}^{b \times B}$ is a transformation matrix mapping the HSI $\mathcal{X} \in \mathbb{R}^{R \times C \times B}$ to its RGB representation $\mathcal{Z} \in \mathbb{R}^{R \times C \times b}$ ($b \ll B$). The tensor product is defined in Section II.

To cope with the ill-posed nature of the HSI restoration task, various prior knowledge of the HSI is proposed to regularize the solution space:

$$\min_{\mathcal{X}} \frac{1}{2} \|\mathcal{Y} - \mathcal{T}_{sa}(\mathcal{X}) - \mathcal{E}\|_F^2 + \frac{1}{2} \|\mathcal{Z} - \mathcal{T}_{sc}(\mathcal{X})\|_F^2 + \lambda \Phi(\mathcal{X}), \quad (3)$$

where $\|\bullet\|_F^2$ stands for the Frobenius norm, the first two data fidelity terms represent the spatial and spectral degradation process respectively, $\Phi(\mathcal{X})$ is a regularization term to enforce the solution with desired property, and λ is a trade-off regularization parameter. The success of the HSI restoration heavily depends on how we choose proper prior knowledge. From the perspective of the data format in the prior, we classify the existing HSI restoration methods into three categories: one-dimensional vector-based sparse representation methods [3]–[8], two-dimensional matrix-based low-rank matrix recovery methods [9]–[18], and three-dimensional tensor-based approximation methods [19]–[31].

Although the existing works have made significant pro-

gresses in HSI restoration, there are three main drawbacks to be improved. Firstly, transforming the multi-dimensional HSI data into a vector or matrix usually breaks the spectral-spatial structural correlation. The recent works [25], [32] consistently indicate that the tensor-based methods substantially preserve the intrinsic structure correlation with better restoration results. Besides, some tensor-based methods are quite heuristic without taking the sparsity prior into consideration, which makes them hard to be extended to other HSI restoration tasks. Secondly, compared with natural 2-D images, the HSI data could provide us extra spectral information. Unfortunately, many HSI restoration methods fall into the ‘trap’ of high spectral correlation, while ignoring the non-local similarity [14], and vice versa [32]. Thus the results of these approaches may be suboptimal. Finally, most of the previous methods only employ the conventional L_1 or nuclear norm as the sparsity constraint for HSI restoration. As a result, each patch is encoded equally. Such a mechanism may not take advantage of the structural difference of image patch sufficiently.

In this work, to overcome the aforementioned drawbacks, we present a unified HSI restoration framework via the weighted low-rank tensor recovery model. The tensor format naturally offers a unified understanding of the vector/matrix-based recovery models. Compared with the state-of-the-art HSI restoration methods, the contributions of the proposed work are as follows:

- We propose a weighted low-rank tensor recovery model for HSI restoration, where the singular values in the core tensor are of different importance and assigned different weights. The simple yet effective weighted operation has immediate physical interpretation, which has been extensively studied in the matrix. We demonstrate that the weighted strategy could be well extended to the tensor and facilitates the HSI modeling.
- Most of the HSI restoration methods encode the spectral or spatial information independently, ignore the spatial-spectral structural correlation. Our method employs the low-rank tensor prior to model the spatial non-local self-similarity and spectral correlation property simultaneously, better preserving the intrinsic spectral-spatial structural correlation. Moreover, we extend WLRTR to the WLRT-RRPCA for the sparse error modeling.
- To our knowledge, this is the first work that *comprehensively* considers the HSI restoration in a unified model. We validate WLRTR on several representative HSI restoration tasks, such as denoising, destriping, deblurring, and super-resolution, and the proposed WLRTR model consistently outperforms the state-of-the-art methods by a large margin. Further, we show that the WLRTR can be well applied to multispectral images.

The related HSI restoration methods are introduced in Section II. Section III presents the weighted low-rank tensor recovery modeling, and analyzes its closed-form solution. Section IV proposes the concrete objective function of each individual HSI restoration task, and gives the corresponding optimization procedures. Extensive experimental results are reported in Section V. Section VI concludes this paper.

II. RELATED WORK

Low-rank Modeling: The low-rank models have been extensively studied in HSI restorations [9]–[12], [14]–[17], [19]–[27]. The two-dimensional low-rank matrix recovery methods have shown great effectiveness to discover the intrinsic low-dimensional structures in high-dimensional HSI data. In [10], by lexicographically ordering the 3-D cube into a 2-D matrix representation along the spectral dimension, Zhang *et al.* proposed a low-rank matrix restoration model for mixed noise removal in HSI. A lot of works follow this research line [11], [12], [14], [15], [18]. To better preserve the spatial-spectral correlation, the low-rank tensors recovery methods have been proposed [21]–[31]. Previous tensor-based methods equally treat each core tensor coefficient, ignoring the fact that each coefficient represents the different correlations across each mode. The reweighting strategy interprets the fine-grained structural discrepancy, and has been proven effective in vector/matrix cases [33], [34], while it has received less attention in tensor-based HSI restorations. In this work, we further take the fine-grained intrinsic sparsity of the core tensor into consideration via reweighting strategy, so as to better encode the structure correlation.

HSI Denoising: Image denoising is a test bed for various techniques. Consequently, numerous approaches for HSI denoising have been proposed [35]–[37]. The spectral correlation and nonlocal self-similarity are two kinds of intrinsic characteristic underlying an HSI. Most previous HSI denoising methods focus on the spectral correlation such as the wavelet methods [4], total variational methods [8], the low-rank matrix recovery methods [10], [11], [14], [38], or the nonlocal self-similarity such as BM4D [39], HOSVD [40] individually. Recently, Peng *et al.* [23] firstly modeled them simultaneously in tensor format. However, the TDL [23] is quite heuristic and short of a concise formulation, and thus lack of the flexibility to other HSI restoration tasks. Several tensor works [24]–[27] follow the research line of [23], and model the sparsity of the core tensor in a principled manner. Interested readers could refer to [15] for detailed background of HSI denoising.

HSI Destriping: Stripe noise is a very common structural noise in HSI. Traditional HSI destriping methods [10], [41]–[44] treated this problem as a denoising task and estimate the image directly with white Gaussian noise assumption. Further, Meng *et al.* [38], [45] hold the point that the stripe line is a kind of structural noise, and introduced the mixture of Gaussians (MoG) noise assumption to accommodate the stripe noise characteristic. On the contrary, some works started from the opposite direction by estimating the stripe noise only [46]–[48]. These methods regarded the stripe noise as a kind of specific image structure with fewer variables and regular patterns, which makes the problem easier to be solved. Our recent work [17] proposed to treat the HSI destriping task as an image decomposition task, in which the clear image and stripe components were treated equally and estimated iteratively. Most of the previous methods are 2-D based methods, failing to capture the spectral coherence. Compared with tensor-based RPCA methods [49], [50], our method further takes the structurally directional property of the sparse error into

Fig. 1: The illustration of the HOSVD.

consideration. For the first time, we introduce the \mathcal{L}_{211} norm (Section IV-B) into the tensor RPCA for structural stripe noise removal. Interested readers could refer to [17] for details.

HSI Deblurring: Natural image deblurring aims to recover a sharp latent image from a blurred one [51], which is a classical and active research field within the last decade. Numerous HSI deblurring methods directly learn natural image priors by assuming the widely used sparsity of image gradients, e.g., Huber-Markov prior [52], the total variation (TV) [53], and Gaussian mixture model (GMM) [54]. Only recently, the spatial-spectral joint total variation has been introduced to HSI deblurring [55], [56]. In general, most previous HSI deblurring methods only exploit the spatial information, while none of them have utilized the non-local self-similarity property in HSI. In this work, we focus on the non-blind HSI deblurring, and show that the additional spectral correlation and non-local information would significantly improve the HSI deblurring performance.

HSI Super-resolution: HSI super-resolution refers to the fusion of a hyperspectral image (low spatial but high spectral-resolution) with a panchromatic/multispectral image (high spatial but low spectral-resolution, usually RGB image). The most popular sparsity promoting methods mainly include the sparse representation [6], [7], [57]–[60] and the matrix factorization approach [5], [61]–[64]. In [6], the authors applied the dictionary learning embedded in the spectral subspace to exploit the sparsity of hyperspectral images. In [5], Dong *et al.* proposed a non-negative structured sparse representation (NSSR) approach with the prior knowledge about spatio-spectral sparsity of the hyperspectral image. Analog to classical super-resolution [65], a sparse matrix factorization method [62] borrowed the idea that both the LR hyperspectral image and HR RGB image share the same coding coefficients. The HR hyperspectral image was then reconstructed by multiplying the learned basis from the HR RGB image and sparse coefficients from the LR hyperspectral image. Recently, Dian *et al.* [32] proposed a non-local sparse Tucker tensor factorization (NLSTF) model for HSI super-resolution. The interested readers can refer to the survey [66].

III. WEIGHTED LOW-RANK TENSOR RECOVERY MODEL

A. Notations and Preliminaries

In this paper, we denote tensors by boldface Euler script letters, e.g., \mathcal{X} . Matrices are represented as boldface capital letters, e.g., \mathbf{X} ; vectors are expressed with boldface lowercase letters, e.g., \mathbf{x} , and scalars are denoted by lowercase letters,

e.g., x . The i -th entry of a vector \mathbf{x} is denoted by x_i , element (i, j) of a matrix \mathbf{X} is denoted by x_{ij} , and element (i, j, k) of a third-order tensor \mathcal{X} is denoted by x_{ijk} .

Fibers are the higher-order analogue of matrix rows and columns. A fiber of an N -dimensional tensor is a 1-D vector defined by fixing all indices but one [67]. A **Slice** of an N -dimensional tensor is a 2-D matrix defined by fixing all but two indices [67]. For a third order tensor, its column, row, and tube fibers, denoted by $\mathbf{x}_{:jk}$, $\mathbf{x}_{i:k}$, and $\mathbf{x}_{ij:}$, respectively.

Definition 1 (Tensor norms) The *Frobenius* norm of an N order tensor $\mathcal{X} \in \mathbb{R}^{I_1 \times I_2 \times \dots \times I_N}$ is the square root of the sum of the squares of all its elements, i.e., $\|\mathcal{X}\|_F = \sqrt{\sum_{i_1=1}^{I_1} \sum_{i_2=1}^{I_2} \dots \sum_{i_N=1}^{I_N} x_{i_1 i_2 \dots i_N}^2}$. The \mathcal{L}_1 norm of an N -order tensor is the sum of the absolute value of all its elements, i.e., $\|\mathcal{X}\|_1 = \sum_{i_1=1}^{I_1} \sum_{i_2=1}^{I_2} \dots \sum_{i_N=1}^{I_N} |x_{i_1 i_2 \dots i_N}|$. These norms for tensor are analogous to the matrix norm.

Definition 2 (Tensor matricization) Matricization, also named as *unfolding or flattening*, is the process of reordering the elements of an N -order tensor into a matrix. The mode- n matricization $\mathbf{X}_{(n)} \in \mathbb{R}^{I_n \times (I_1 \dots I_{n-1} I_{n+1} \dots I_N)}$ of a tensor $\mathcal{X} \in \mathbb{R}^{I_1 \times I_2 \times \dots \times I_N}$ is obtained by taking all the mode- n fibers to be the columns of the resulting matrix.

Definition 3 (Tensor product) Here we just consider the tensor n -mode product, i.e., multiplying a tensor by a matrix in mode n , which will be used in HOSVD latter. Interested readers can refer to Bader and Kolda [67] for a full treatment of tensor multiplication. For a tensor $\mathcal{X} \in \mathbb{R}^{I_1 \times I_2 \times \dots \times I_N}$, its n -mode product with a matrix $\mathbf{U} \in \mathbb{R}^{J \times I_n}$ is denoted by $\mathcal{Z} = \mathcal{X} \times_n \mathbf{U}$, and $\mathcal{Z} \in \mathbb{R}^{I_1 \times \dots \times I_{n-1} \times J \times I_{n+1} \times \dots \times I_N}$. Each element in \mathcal{Z} can be represented as

$$z_{i_1 \dots i_{n-1} j i_{n+1} \dots i_N} = \sum_{i_n=1}^{I_n} x_{i_1 i_2 \dots i_N} u_{j i_n}. \quad (4)$$

Definition 4 (Tensor SVD) The Tucker decomposition is a kind of higher-order SVD (HOSVD), which decomposes a tensor into a core tensor multiplied by a matrix along each mode [19]:

$$\mathcal{X} = \mathcal{S} \times_1 \mathbf{U}_1 \times_2 \mathbf{U}_2 \times_3 \dots \times_N \mathbf{U}_N, \quad (5)$$

where $\mathcal{X} \in \mathbb{R}^{I_1 \times I_2 \times \dots \times I_N}$, $\mathcal{S} \in \mathbb{R}^{I_1 \times I_2 \times \dots \times I_N}$ is the *core tensor* similar to the singular values in matrix, and its intensity shows the level of interaction between different components, $\mathbf{U}_i \in \mathbb{R}^{I_i \times I_i}$ is the column-wise orthonormal factor matrix and can be regarded as the principal components in each mode. The main purpose of our work is to estimate the core tensors \mathcal{S} and the clean image tensor \mathcal{X} in presence of the degraded tensor \mathcal{Y} , as shown in Fig. 1.

B. WLRTTR for 3-D HSI Restoration

1) *Why Low-rank Tensor Recovery:* One major shortcoming of 2-D low-rank is that it can only work in the presence of 2-way (matrix) data. However, the real data, such as HSIs and color images, are ubiquitously in three-dimensional way, also referred to as 3-order tensor. To preserve the structural information, we introduce the low-rank tensor recovery model to handle the tensor data by taking advantage of its multi-dimensional structure.

Fig. 2: HOSVD analysis on 3-order tensor. (a) Singular values of core tensor bigger than 1. (b) Plot of the singular values of both clean and noisy tensors.

We apply the HOSVD on the tensor to see how the sparsity of its higher-order singular value distributes in 3-order tensor, namely its higher-order low-rank property. In Fig. 2, we give a visualization for facilitating the understanding of the sparsity in the core tensor. There are two observations we make here. First, Figure 2(a) shows the location of singular values in the core tensor, according to their magnitudes. In Fig. 2(a), we can observe that singular values of the core tensor exhibit significant sparsity with different degrees along each mode. More specifically, the magnitude of the singular value shows a general descending tendency along the 2-mode and 3-mode. Along the 2-mode, due to the strong redundancy of the non-local cubics, the coefficients in the core tensor along this mode tend to be decreasing very fast to zero. And along the 3-mode, due to the high spectral correlation, the coefficients in the core tensor along this mode tend to decrease to zero with relatively slow speed. Second, from Fig. 2(b), we can observe that singular values of the clean cubic exist much more sparsity than those of the noisy cubics, and follow an extremely sharp exponential decay rule. Moreover, the intrinsic sparsity of the higher-order singular values of the 3-D cubic is much more apparent than that of the singular values of the 2-D patch [27]. Therefore, it is natural to use the tensor low-rank model for HSIs recovery problem.

In Fig. 3, we give a visual comparison between the 3-order cubic recovery and 2-order matrix recovery. Figure 3(b) shows the result of 2-D spatial low-rank recovery result, where the low-rank matrix is formed via spatial non-local similar patches. Figure 3(c) shows the result of 2-D spectral low-rank recovery result, where the low-rank matrix is formed via spectral similar bands. Figure 3(d) shows the result of the proposed low-rank tensor recovery. It can be inferred from the visual appearance and PSNR values that the proposed low-rank tensor recovery method has an obvious advantage over low-rank matrix recovery methods in terms of both noise reduction and texture preserving.

2) *Weighted Low-rank Tensor Recovery Model*: For the problem (3), the variable splitting technique [68] is usually introduced to decouple the data fidelity term and regularization term by introducing an auxiliary variable \mathcal{L}_i . Consequently, for the regularization-related subproblem, it can be regarded as an image denoising problem as follow:

$$\Phi(\mathcal{L}_i) = \sum_i \frac{1}{\sigma_i^2} \|\mathcal{R}_i \mathcal{X} - \mathcal{L}_i\|_F^2 + \text{rank}(\mathcal{L}_i), \quad (6)$$

Fig. 3: The advantage of the low-rank tensor recovery over low-rank matrix recovery. (a) Simulated noisy image under Gaussian noise ($\sigma = 10$, PSNR = 28.13dB). (b) 2-D low-rank matrix recovery result via spatial non-local similarity (PSNR = 37.56dB). (c) 2-D low-rank matrix recovery result via spectral correlation (PSNR = 39.18dB). (d) 3-D low-rank tensor recovery result (PSNR = 42.95dB).

where $\mathcal{R}_i \mathcal{X}$ is the constructed 3-order tensor for each exemplar cubic at location i , and our goal is to estimate the corresponding low-rank approximation \mathcal{L}_i under noise variance σ_i^2 .

The low-rank regularization has been widely used in matrix recovery, and the nuclear norm is usually introduced as the surrogate functional of low-rank constraint. In this work, we borrow this notion in 2-D matrix to define the tensor nuclear norm of \mathcal{L}_i as $\|\mathcal{L}_i\|_* = \sum_j |\sigma_j(\mathcal{L}_i)|_1$, namely the sum of its higher-order singular values. Then, the low-rank tensor \mathcal{L}_i can be recovered by solving the following optimization problem:

$$\hat{\mathcal{L}}_i = \arg \min_{\mathcal{L}_i} \frac{1}{\sigma_i^2} \|\mathcal{R}_i \mathcal{X} - \mathcal{L}_i\|_F^2 + \|\mathcal{L}_i\|_*. \quad (7)$$

However, this tensor nuclear norm has not considered the fine-grained sparsity configurations inside the coefficient tensor. As seen in Fig. 2(b), the singular values of clean tensor $\mathcal{R}_i \mathcal{X}$ exhibit strong sparsity, in which most of the singular values are close to zero. For the singular values of its corresponding noisy tensor, the larger singular values are close to the singular values of the clean tensor, while the small and trivial singular values are obviously larger than the singular values of the clean tensor. This phenomenon motivates us to penalize the larger singular values less and small singular values more. Thus, we replace the conventional tensor nuclear norm with the weighted one on \mathcal{L}_i :

$$\hat{\mathcal{L}}_i = \arg \min_{\mathcal{L}_i} \frac{1}{\sigma_i^2} \|\mathcal{R}_i \mathcal{X} - \mathcal{L}_i\|_F^2 + \|\mathcal{L}_i\|_{\mathbf{w},*}. \quad (8)$$

where $\|\mathcal{L}_i\|_{\mathbf{w},*} = \sum_j |w_j \sigma_j(\mathcal{L}_i)|_1$, $\mathbf{w} = [w_1, \dots, w_n]$ and w_j is a non-negative weight assigned to $\sigma_j(\mathcal{L}_i)$. The intuitions behind this weighted process are two-folds. On the one hand, larger singular values corresponding to the major projection orientations should be penalized less to preserve the major data components. On the other hand, the success of the reweighting strategy, where the regularization parameter is adaptive and inversely proportional to the underlying signal magnitude, has been verified in the various computer vision task [34], [69]. For a small value after t iteration, due to the reweighted process in sparsity constraint, it will enforce a larger reweighting factor in the next $t + 1$ iteration, which would naturally result in a sparser result. In this work, we set

$$w_j^{t+1} = c / (|\sigma_j^t(\mathcal{L}_i)| + \varepsilon), \quad (9)$$

Fig. 4: Effectiveness of the adaptive weighted strategy. (a) Original clean image. (b) Simulated noisy image band 15 under Gaussian noise (sigma=30, PSNR = 18.59dB). (c) Denoising result of the proposed method without adaptive weighted strategy (PSNR = 41.27dB). (d) Denoising result of the proposed method (PSNR = 41.85dB).

where $c = 0.04$ is a constant, and ε is a small constant to avoid dividing by zero. In Fig. 4, we give a visual comparison between LRTR model with/without the weighted strategy. The result of Fig. 4(d) exhibits sharper edges than that of without reweighted strategy, which demonstrates the effectiveness of the sparsity reweight strategy in higher-order singular values.

3) *Analytical solution of (8)*: By replacing \mathcal{L}_i in (8) with the corresponding HOSVD, we obtain the following problem:

$$\{\hat{\mathcal{S}}_i, \hat{U}_1, \hat{U}_2, \hat{U}_3\} = \arg \min_{\mathcal{S}_i, U_1, U_2, U_3} \|\mathcal{R}_i \mathcal{X} - \mathcal{S}_i \times_1 U_1 \times_2 U_2 \times_3 U_3\|_F^2 \quad (10)$$

$$+ \sigma_i^2 \|\mathbf{w}_i \circ \mathcal{S}_i\|_1, \text{ s.t. } U_j^T U_j = \mathbf{I}, j = 1, 2, 3,$$

where \circ denotes the element-wise multiplication, and j means the mode index of a 3-order tensor. There are four variables U_1, U_2 and U_3 along with \mathcal{S}_i to be estimate iteratively.

► **Update singular matrix U_j** : Since the optimization of U_1, U_2 and U_3 are similar, we take the U_1 as an example. Dropping out the irrelevant variables from U_1 in Eq. (10), we can get the following subproblem:

$$\hat{U}_1 = \arg \min_{U_1^T U_1 = \mathbf{I}} \|\mathcal{A}_i - \mathcal{S}_i \times_1 U_1 \times_2 U_2 \times_3 U_3\|_F^2, \quad (11)$$

where $\mathcal{A}_i = \mathcal{R}_i \mathcal{X} \in \mathbb{R}^{I_1 \times I_2 \times I_3}$ for simplicity, $U_1 \in \mathbb{R}^{I_1 \times r_1}$, $U_2 \in \mathbb{R}^{I_2 \times r_2}$ and $U_3 \in \mathbb{R}^{I_3 \times r_3}$, we can transform the Eq. (11) into the following matrix-vector product:

$$\hat{U}_1 = \arg \min_{U_1^T U_1 = \mathbf{I}} \|\text{vec}(\mathcal{A}_i) - (U_3 \otimes U_2 \otimes U_1) \text{vec}(\mathcal{S}_i)\|_2^2, \quad (12)$$

where \otimes denotes the Kronecker product, and $\text{vec}(\cdot)$ is the vectorization of the given variable. Since the $U_3 \otimes U_2 \otimes U_1$ has orthonormal columns, we have $\text{vec}(\mathcal{S}_i) = (U_3 \otimes U_2 \otimes U_1)^T \text{vec}(\mathcal{A}_i) = (U_3^T \otimes U_2^T \otimes U_1^T) \text{vec}(\mathcal{A}_i)$. Thus, we can further obtain

$$\hat{U}_1 = \arg \min_{U_1^T U_1 = \mathbf{I}} \|\mathbf{I} - (U_3 \otimes U_2 \otimes U_1)(U_3^T \otimes U_2^T \otimes U_1^T)\|_2^2 \text{vec}(\mathcal{A}_i)\|_2^2. \quad (13)$$

If $\mathcal{Q} = U_3 \otimes U_2 \otimes U_1$ has orthonormal columns then we have

$$\begin{aligned} & \|(\mathbf{I} - \mathcal{Q}\mathcal{Q}^T) \text{vec}(\mathcal{A}_i)\|_2^2 \\ &= \langle \text{vec}(\mathcal{A}_i), \text{vec}(\mathcal{A}_i) \rangle - 2 \langle \text{vec}(\mathcal{A}_i), \mathcal{Q}\mathcal{Q}^T \text{vec}(\mathcal{A}_i) \rangle \\ &+ \langle \mathcal{Q}\mathcal{Q}^T \text{vec}(\mathcal{A}_i), \mathcal{Q}\mathcal{Q}^T \text{vec}(\mathcal{A}_i) \rangle \\ &= \|\text{vec}(\mathcal{A}_i)\|_2^2 - \|\mathcal{Q}^T \text{vec}(\mathcal{A}_i)\|_2^2. \end{aligned}$$

Thus, the minimization of problem Eq. (13) is equivalent to the following maximization problem:

$$\hat{U}_1 = \arg \max_{U_1^T U_1 = \mathbf{I}} \|(U_3 \otimes U_2 \otimes U_1)^T \text{vec}(\mathcal{A}_i)\|_2^2. \quad (14)$$

According to the following reshaping

$$\begin{aligned} & \| (U_3 \otimes U_2 \otimes U_1)^T \text{vec}(\mathcal{A}_i) \|_2^2 \\ &= \| U_1^T \mathcal{A}_{(1)} (U_3 \otimes U_2) \|_F^2 \\ &= \| U_2^T \mathcal{A}_{(2)} (U_3 \otimes U_1) \|_F^2 \\ &= \| U_3^T \mathcal{A}_{(3)} (U_2 \otimes U_1) \|_F^2. \end{aligned} \quad (15)$$

Thus, by assuming $\mathbf{W} = \mathcal{A}_{(1)}(U_3 \otimes U_2)$, the objective function in (14) can be rewritten as:

$$\hat{U}_1 = \arg \max_{U_1^T U_1 = \mathbf{I}} \langle U_1, \mathbf{W} \rangle. \quad (16)$$

Assume that the singular value decomposition of $\mathbf{W} = \mathbf{P}\mathbf{\Sigma}\mathbf{Q}^T$, thus we have

$$\langle U_1, \mathbf{W} \rangle = \text{tr}(U_1^T \mathbf{W}) = \text{tr}(U_1^T \mathbf{P}\mathbf{\Sigma}\mathbf{Q}^T) = \text{tr}(\mathbf{Q}^T U_1^T \mathbf{P}\mathbf{\Sigma}). \quad (17)$$

Since \mathbf{Q}, U_1 and \mathbf{P} are both orthogonal, and $\mathbf{Z} = \mathbf{Q}^T U_1^T \mathbf{P}$ is also orthogonal with each element $|z_{ij}| \leq 1, \forall i, j$. Thus,

$$\begin{aligned} \text{tr}(\mathbf{Z}\mathbf{\Sigma}) &= z_{11}\sigma_1 + z_{22}\sigma_2 + \dots + z_{nn}\sigma_n \\ &\leq |z_{11}\sigma_1 + z_{22}\sigma_2 + \dots + z_{nn}\sigma_n| \\ &\leq |z_{11}\sigma_1| + |z_{22}\sigma_2| + \dots + |z_{nn}\sigma_n| \\ &\leq |z_{11}|\sigma_1 + |z_{22}|\sigma_2 + \dots + |z_{nn}|\sigma_n \\ &\leq |\sigma_1| + |\sigma_2| + \dots + |\sigma_n| \\ &= \sigma_1 + \sigma_2 + \dots + \sigma_n. \end{aligned} \quad (18)$$

The equality is achieved when there exists $z_{11} = z_{22} = \dots = z_{nn} = 1$. That is to say \mathbf{Z} is the identity matrix. Therefore, we can obtain $U_1 = \mathbf{P}\mathbf{Q}^T$. Similar optimization procedures are performed on U_2 and U_3 . The reference [25] has also provided a solution to the optimize U_1, U_2 and U_3 via the *von Neumann's trace inequality for the matrix* [70]. The interested reader could refer to the details in [25].

► **Update core tensor \mathcal{S}_i** : By ignoring terms independent of core tensor \mathcal{S}_i in Eq. (10), we obtain following subproblem:

$$\hat{\mathcal{S}}_i = \arg \min_{\mathcal{S}_i} \|\mathcal{R}_i \mathcal{X} - \mathcal{S}_i \times_1 U_1 \times_2 U_2 \times_3 U_3\|_F^2 + \sigma_i^2 \|\mathbf{w}_i \circ \mathcal{S}_i\|_1. \quad (19)$$

We follow the technique in [25] where $\|\mathcal{S}_i \times U\|_F^2 = \|\mathcal{S}_i\|_F^2, \forall U^T U = \mathbf{I}$. That is to say, the product of a tensor by the columns orthogonal matrix does not change the strength of the signal. Therefore, we can obtain

$$\hat{\mathcal{S}}_i = \arg \min_{\mathcal{S}_i} \|\mathcal{S}_i - \mathcal{O}_i\|_F^2 + \sigma_i^2 \|\mathbf{w}_i \circ \mathcal{S}_i\|_1, \quad (20)$$

where $\mathcal{O}_i = (\mathcal{R}_i \mathcal{X}) \times_1 U_1^T \times_2 U_2^T \times_3 U_3^T$ is for simplicity. Assume that each coefficient in the core tensor as s_{ijk} and o_{ijk} , respectively, the problem (20) can be converted into the scalar format. Since the singular value in the HOSVD could be either negative or positive, we first consider the situation that $s_{ijk} \geq 0$:

$$\begin{aligned} & \min_{s_{ijk}} (s_{ijk} - o_{ijk})^2 + \sigma_i^2 |w_{ijk} s_{ijk}| \\ &\Leftrightarrow \min_{s_{ijk}} (s_{ijk} - o_{ijk})^2 + \sigma_i^2 w_{ijk} s_{ijk} \\ &\Leftrightarrow \min_{s_{ijk}} \left(s_{ijk} - \left(o_{ijk} - \frac{\sigma_i^2 w_{ijk}}{2} \right) \right)^2. \end{aligned} \quad (21)$$

It is easy to derive its closed-form solution as:

$$s_{ijk} = \max \left(o_{ijk} - \frac{\sigma_i^2 w_{ijk}}{2}, 0 \right). \quad (22)$$

Fig. 5: Illustration of HSI stripe mode-1 unfolding. (a) Original HSI cubic with vertical stripe; (b) Mode-1 unfolding matrix.

Furthermore, we incorporate the condition $s_{ijk} < 0$ into consideration, we can obtain the final solution:

$$\mathcal{S}_i = \text{sign}(\mathcal{O}_i) \max(|\mathcal{O}_i| - w_i \sigma_i^2 / 2, 0). \quad (23)$$

The variables $\mathbf{U}_1, \mathbf{U}_2, \mathbf{U}_3$, and \mathcal{S}_i have been updated alternately with closed-form solutions. The main procedure of the alternating minimization of each variable is similar to [25]. It is worth noting that, the Eq. (8) is very similar to that of the 2D WNNM [72], which employs the *von Neuman's Trace inequality for matrix* [70] to solve the problem. However, the *von Neuman's Trace inequality for tensor* [71] cannot be directly applied to solve the Eq. (8). The *von Neuman's Trace inequality holds for tensor* with two additional conditions: the diagonal condition and proportional condition. Interested readers could refer to [71] for details. The diagonal condition is satisfied from both theoretical viewpoint (Tucker decomposition can be regarded as a special case of block term decomposition (BTD)) and experimental viewpoint (Fig. 2). As for the proportional condition, such a strong assumption can not be easily satisfied in HSI. The exploration toward the unified optimization for both the 2D and higher-order WNNM would be an interested topic.

IV. HSI RESTORATION WITH WLRTR MODEL

A. WLRTR for HSI Denoising

For HSI denoising, we only consider the random noise \mathcal{N} with an identity tensor operator. Thus, by combining the data fidelity term $\frac{1}{2} \|\mathcal{Y} - \mathcal{X}\|_F^2$ with the WLRTR prior, the Eq. (3) can be formulated as the following minimization problem:

$$\begin{aligned} \{\hat{\mathcal{X}}, \hat{\mathcal{S}}_i, \hat{\mathbf{U}}_j\} = \arg \min_{\mathcal{X}, \mathcal{S}_i, \mathbf{U}_j} \frac{1}{2} \|\mathcal{Y} - \mathcal{X}\|_F^2 + \\ \eta \sum_i (\|\mathcal{R}_i \mathcal{X} - \mathcal{S}_i \times_1 \mathbf{U}_1 \times_2 \mathbf{U}_2 \times_3 \mathbf{U}_3\|_F^2 + \sigma_i^2 \|\mathbf{w}_i \circ \mathcal{S}_i\|_1). \end{aligned} \quad (24)$$

The alternating minimization strategy is introduced to solve (24). The closed-form solutions of \mathcal{S}_i and \mathbf{U}_j related sub-problems (10) have been analyzed. Thus, we can reconstruct the whole image \mathcal{X} by solving the following sub-problem:

$$\hat{\mathcal{X}} = \arg \min_{\mathcal{X}} \frac{1}{2} \|\mathcal{Y} - \mathcal{X}\|_F^2 + \eta \sum_i \|\mathcal{R}_i \mathcal{X} - \mathcal{S}_i \times_1 \mathbf{U}_1 \times_2 \mathbf{U}_2 \times_3 \mathbf{U}_3\|_F^2. \quad (25)$$

Eq. (25) is a quadratic optimization problem admitting a closed-form solution:

$$\mathcal{X} = (I + \eta \sum_i \mathcal{R}_i^T \mathcal{R}_i)^{-1} (\mathcal{Y} + \eta \sum_i (\mathcal{R}_i^T \mathcal{S}_i) \times_1 \mathbf{U}_1 \times_2 \mathbf{U}_2 \times_3 \mathbf{U}_3), \quad (26)$$

where $\eta \sum_i \mathcal{R}_i^T \mathcal{R}_i$ denotes the number of overlapping cubics that cover the pixel location, and $\eta \sum_i (\mathcal{R}_i^T \mathcal{S}_i) \times_1 \mathbf{U}_1 \times_2 \mathbf{U}_2 \times_3 \mathbf{U}_3$ means the sum value of

Algorithm 1 WLRTR for HSI denoising

Require: Noisy image \mathcal{Y}

```

7:       Step3: Solve Eq. (11) for the singular matrix  $\mathbf{U}_j$ ;
8:       Step4: Estimate the core tensor  $\mathcal{S}_i$  via Eq. (23);
9:     end for
10:    Step5: Reconstruct the whole image  $\mathcal{X}$  via Eq.(26).
11:  end for

```

Ensure: Clean image \mathcal{X}

all overlapping reconstruction cubics that cover the pixel location. Eq. (26) can be computed in tensor format efficiently.

After obtaining an improved estimate of the unknown image, the low-rank tensor approximation can be updated by Eq. (10). The updated \mathcal{S}_i and \mathbf{U}_j are fed back to Eq. (26) improving the estimate of \mathcal{X} . Such process is iterated until the convergence. The overall procedure is summarized in **Algorithm 1**.

B. WLRTR-RPCA for HSI Destriping

In real HSI, there always exists system structural noise such as stripe noise. The stripes in HSIs via push-broom imaging spectrometer are always non-periodic, and arise from the unstable detectors during a scanning cycle. Therefore, it is natural for us to borrow the RPCA model [9] to accommodate the sparse error component, mainly the stripe noise \mathcal{E} . The RPCA has shown its robustness in presence of the sparse error, such as background subtraction [72], structure noise removal [17], and face recognition under occlusion [73], since it has taken the sparse error into consideration.

In this section, we extend the WLRTR to the WLRTR-RPCA for stripe noise removal. For the image prior, we will utilize the weighted low-rank tensor prior to model them. While for the stripe noise with obviously directional characteristic, as shown in Fig. 5, we argue the $L_{2,1}$ -norm with direction discriminative ability is more appropriate than L_1 -norm. Since $L_{2,1}$ -norm $\|\mathcal{E}\|_{2,1} = \sum_{j=1}^C \sqrt{\sum_{i=1}^R (E_{ij})^2}$ encourages the intensity of columns to be zero, the underlying assumption here is that the corruptions are sample-specific, i.e., some data vectors are corrupted and the others are clean, just corresponding to the broken and intact detectors, respectively.

In this work, we extend the matrix $L_{2,1}$ -norm to its 3-order tensor case $\|\mathcal{E}\|_{2,1,1} = \sum_{k=1}^B \sum_{j=1}^C \sqrt{\sum_{i=1}^R (E_{ijk})^2}$, and incorporate it into the WLRTR model as follow:

$$\begin{aligned} \{\hat{\mathcal{X}}, \hat{\mathcal{E}}, \hat{\mathcal{S}}_i, \hat{\mathbf{U}}_j\} = \arg \min_{\mathcal{X}, \mathcal{E}, \mathcal{S}_i, \mathbf{U}_j} \frac{1}{2} \|\mathcal{Y} - \mathcal{X} - \mathcal{E}\|_F^2 + \rho \|\mathcal{E}\|_{2,1,1} + \\ \eta \sum_i (\|\mathcal{R}_i \mathcal{X} - \mathcal{S}_i \times_1 \mathbf{U}_1 \times_2 \mathbf{U}_2 \times_3 \mathbf{U}_3\|_F^2 + \sigma_i^2 \|\mathbf{w}_i \circ \mathcal{S}_i\|_1), \end{aligned} \quad (27)$$

where ρ and η are the regularization parameters. The WLRTR-RPCA model (27) is simple and easy to understand, in which the local sparsity, non-local similarity, and spectral consistency of the images are utilized via the tensor low-rank prior, whereas the stripe noise is well depicted by the $L_{2,1}$ -norm, so that the mixed random and stripe noise can be separated from the images satisfactorily.

Algorithm 2 WLRTR-RPCA for HSI destriping

Require: Noisy image \mathcal{Y}

- 1: **procedure** DESTRIPIING
- 2: **Initialize:** Set parameters η and ρ ; $\mathcal{X}^{(1)} = \mathcal{Y}$;
- 3: **for** $n=1:N$ **do**
- 4: Step 1: Update sparse error \mathcal{E} by solving (28);
- 5: Step 2: Update clean image \mathcal{X} by **Algorithm 1**.
- 6: **end for**

Ensure: Clean image \mathcal{X} and stripe component \mathcal{E} .

The procedures of estimation \mathcal{S}_i and \mathcal{X} are similar with the **Algorithm 1**. Here, we show how we estimate \mathcal{E} . Once \mathcal{S}_i and \mathcal{X} have been estimated, we can estimate \mathcal{E} by solving the following sub-problem:

$$\hat{\mathcal{E}} = \arg \min_{\mathcal{E}} \frac{1}{2} \|\mathcal{Y} - \mathcal{X} - \mathcal{E}\|_F^2 + \rho \|\mathcal{E}\|_{2,1,1}, \quad (28)$$

It is hard to directly obtain the final result. However, we have the following **Lemma** [74]: Let $\mathcal{Q} = [\mathbf{q}_1, \mathbf{q}_2, \dots, \mathbf{q}_i, \dots]$ be a given matrix and $\|\bullet\|_F$ be the Frobenius norm. If $\hat{\mathbf{W}}$ is the optimal solution of

$$\hat{\mathbf{W}} = \arg \min_{\mathbf{W}} \frac{1}{2} \|\mathbf{W} - \mathcal{Q}\|_F^2 + \mu \|\mathbf{W}\|_{2,1}$$

then the i -th column of $\hat{\mathbf{W}}$ is

$$\hat{\mathbf{W}}(:, i) = \begin{cases} \frac{\|\mathbf{q}_i\| - \mu}{\|\mathbf{q}_i\|} \mathbf{q}_i, & \text{if } \mu \leq \|\mathbf{q}_i\|, \\ 0, & \text{otherwise.} \end{cases}$$

Thus, it is natural for us to unfold the tensors into the matrix (tensor matricization) so that we can apply **Lemma** directly. By unfolding of the tensors along mode-1, Eq. (28) is converted into the equivalent problem

$$\hat{\mathbf{E}}_{(1)} = \arg \min_{\mathbf{E}_{(1)}} \|\mathbf{Y}_{(1)} - \mathbf{X}_{(1)} - \mathbf{E}_{(1)}\|_F^2 + \rho \|\mathbf{E}_{(1)}\|_{2,1}. \quad (29)$$

The Eq. (29) can be solved efficiently via **Lemma**. It is worth noting that we chose the mode-1 unfolding since only in this way the resulting matrix still preserves the directional characteristic [Fig. 5(b)], while mode-2 and mode-3 unfolding may lose this property. After we obtain the sparse error matrix $\hat{\mathbf{E}}_{(1)}$, we fold it into the tensor format. The overall procedure is summarized in **Algorithm 2**.

C. WLRTR for HSI Deblurring

For HSI deblurring, we only consider the random noise \mathcal{N} with the blurring operator. Thus, by combining the data fidelity term $\frac{1}{2} \|\mathcal{Y} - \mathcal{T}(\mathcal{X})\|_F^2$ with the WLRTR prior, the Eq. (3) can be formulated as the following minimization problem:

$$\left\{ \hat{\mathcal{X}}, \hat{\mathcal{S}}_i, \hat{\mathcal{U}}_j \right\} = \arg \min_{\mathcal{X}, \mathcal{S}_i, \mathcal{U}_j} \frac{1}{2} \|\mathcal{Y} - \mathcal{X} * \mathcal{H}\|_F^2 + \quad (30)$$

$$\eta \sum_i (\|\mathcal{R}_i \mathcal{X} - \mathcal{S}_i \times_1 \mathbf{U}_1 \times_2 \mathbf{U}_2 \times_3 \mathbf{U}_3\|_F^2 + \sigma_i^2 \|\mathbf{w}_i \circ \mathcal{S}_i\|_1),$$

where $*$ denotes the convolution operator, and \mathcal{H} is a linear shift-invariant point spread function (PSF). Here, we do not take the stripe noise component \mathcal{E} into consideration. Joint destriping and deblurring for HSI is another much harder problem, which is out of the scope of this work. For the problem (30), we employ the alternating direction method of

Algorithm 3 WLRTR for HSI deblurring

- Ensure:**
- Clean image
- \mathcal{X}
- .
-

multipliers (ADMM) [68] by introducing auxiliary variable $\mathcal{B} = \mathcal{X}$ to decouple the fidelity from regularization term:

$$\hat{\mathcal{B}} = \arg \min_{\mathcal{B}} \frac{1}{2} \|\mathcal{Y} - \mathcal{B} * \mathcal{H}\|_F^2 + \frac{\alpha}{2} \|\mathcal{B} - \mathcal{X} - \frac{\mathcal{J}}{\alpha}\|_F^2 \quad (31a)$$

$$\hat{\mathcal{X}} = \arg \min_{\mathcal{X}} \frac{\alpha}{2} \|\mathcal{B} - \mathcal{X} - \frac{\mathcal{J}}{\alpha}\|_F^2 + \eta \sum_i \|\mathcal{R}_i \mathcal{X} - \mathcal{S}_i \times_1 \mathbf{U}_1 \times_2 \mathbf{U}_2 \times_3 \mathbf{U}_3\|_F^2 \quad (31b)$$

$$\hat{\mathbf{U}}_j = \arg \min_{\mathbf{U}_j^T \mathbf{U}_j = \mathbf{I}} \|\mathcal{R}_i \mathcal{X} - \mathcal{S}_i \times_1 \mathbf{U}_1 \times_2 \mathbf{U}_2 \times_3 \mathbf{U}_3\|_F^2 \quad (31c)$$

$$\hat{\mathcal{S}}_i = \arg \min_{\mathcal{S}_i} \|\mathcal{R}_i \mathcal{X} - \mathcal{S}_i \times_1 \mathbf{U}_1 \times_2 \mathbf{U}_2 \times_3 \mathbf{U}_3\|_F^2 + \sigma_i^2 \|\mathbf{w}_i \circ \mathcal{S}_i\|_1, \quad (31d)$$

where \mathcal{J} is the corresponding Lagrangian multiplier, and α is a positive scalar. The Eq. (31a) performs the image deconvolution, Eq. (31b) means the image denoising process, and Eq. (31c) and (31d) denote the low-rank tensor approximation.

According to Plancherel's theorem [75], the sum of the square of a function equals the sum of the square of its Fourier transform. In view of the convolution operator in Eq. (31a), we operate in the frequency domain using 3-D fast Fourier transforms (3-D FFT) to make the computation efficient. Thus, we can transform the Eq. (31a) into the following:

$$\mathcal{F}(\hat{\mathcal{B}}) = \arg \min_{\mathcal{F}(\mathcal{B})} \frac{1}{2} \|\mathcal{F}(\mathcal{Y}) - \mathcal{F}(\mathcal{B}) \circ \mathcal{F}(\mathcal{H})\|_F^2 + \frac{\alpha}{2} \|\mathcal{F}(\mathcal{B}) - \mathcal{F}(\mathcal{X}) - \mathcal{F}(\frac{\mathcal{J}}{\alpha})\|_F^2. \quad (32)$$

The closed-form solution of Eq. (32) can be expressed as:

$$\hat{\mathcal{B}} = \mathcal{F}^{-1} \left(\frac{\mathcal{F}^*(\mathcal{H}) \circ \mathcal{F}(\mathcal{Y}) + \alpha \mathcal{F}(\mathcal{X}) + \mathcal{F}(\mathcal{J})}{\mathcal{F}^*(\mathcal{H}) \circ \mathcal{F}(\mathcal{H}) + \alpha \mathcal{I}} \right), \quad (33)$$

where \mathcal{F} , \mathcal{F}^* and \mathcal{F}^{-1} denote the FFT operator, its conjugate and its inverse, respectively. The solution of \mathcal{X} in Eq. (31b) can be calculated similar to that of Eq. (25), and the low-rank tensor approximation \mathcal{S}_i and \mathbf{U}_j can be updated by solving Eq. (10). Finally, the Lagrangian multipliers and penalization parameter are updated as follows:

$$\begin{cases} \mathcal{J}^{k+1} = \mathcal{J}^k + \alpha (\mathcal{X} - \mathcal{B}^{k+1}) \\ \alpha^{k+1} = \delta \cdot \alpha^k. \end{cases} \quad (34)$$

The overall procedure is summarized in **Algorithm 3**.

D. WLRTR for HSI Super-Resolution

For HSI super-resolution, we consider the random noise \mathcal{N} with both the blurring and downsampling in spatial domain \mathcal{Y} , as well as downsampling in spectral domain \mathcal{Z} . Thus, the Eq. (3) can be formulated as the following minimization problem:

$$\left\{ \hat{\mathcal{X}}, \hat{\mathcal{S}}_i, \hat{\mathcal{U}}_j \right\} = \arg \min_{\mathcal{X}, \mathcal{S}_i, \mathcal{U}_j} \frac{1}{2} \|\mathcal{Y} - \mathcal{T}_{sa}(\mathcal{X})\|_F^2 + \frac{1}{2} \|\mathcal{Z} - \mathcal{T}_{se}(\mathcal{X})\|_F^2 + \eta \sum_i (\|\mathcal{R}_i \mathcal{X} - \mathcal{S}_i \times_1 \mathbf{U}_1 \times_2 \mathbf{U}_2 \times_3 \mathbf{U}_3\|_F^2 + \sigma_i^2 \|\mathbf{w}_i \circ \mathcal{S}_i\|_1). \quad (35)$$

Ensure: Clean image  $\mathcal{X}$ .

```

Since the variable splitting methods could separate each term with physical meanings, for the problem HSI super-resolution with both spatial and spectral degradations, we also employ the ADMM [68] by introducing two auxiliary variables $\mathcal{Q} = \mathcal{X}$ and $\mathcal{G} = \mathcal{X}$ to decouple the two data fidelity terms from the regularization term as follow:

$$\hat{\mathcal{Q}} = \arg \min_{\mathcal{Q}} \frac{1}{2} \|\mathcal{Y} - \mathcal{T}_{sa}(\mathcal{Q})\|_F^2 + \frac{\beta}{2} \|\mathcal{Q} - \mathcal{X} - \frac{\mathcal{J}_1}{\beta}\|_F^2 \quad (36a)$$

$$\hat{\mathcal{G}} = \arg \min_{\mathcal{G}} \frac{1}{2} \|\mathcal{Z} - \mathcal{T}_{se}(\mathcal{G})\|_F^2 + \frac{\gamma}{2} \|\mathcal{G} - \mathcal{X} - \frac{\mathcal{J}_2}{\gamma}\|_F^2 \quad (36b)$$

$$\hat{\mathcal{X}} = \arg \min_{\mathcal{X}} \eta \sum_i \|\mathcal{R}_i \mathcal{X} - \mathcal{S}_i \times_1 \mathbf{U}_1 \times_2 \mathbf{U}_2 \times_3 \mathbf{U}_3\|_F^2 + \frac{\beta}{2} \|\mathcal{Q} - \mathcal{X} - \frac{\mathcal{J}_1}{\beta}\|_F^2 + \frac{\gamma}{2} \|\mathcal{G} - \mathcal{X} - \frac{\mathcal{J}_2}{\gamma}\|_F^2 \quad (36c)$$

$$\hat{U}_j = \arg \min_{U_j^T U_j = I} \|\mathcal{R}_i \mathcal{X} - \mathcal{S}_i \times_1 \mathbf{U}_1 \times_2 \mathbf{U}_2 \times_3 \mathbf{U}_3\|_F^2 \quad (36d)$$

$$\hat{\mathcal{S}}_i = \arg \min_{\mathcal{S}_i} \|\mathcal{R}_i \mathcal{X} - \mathcal{S}_i \times_1 \mathbf{U}_1 \times_2 \mathbf{U}_2 \times_3 \mathbf{U}_3\|_F^2 + \sigma_i^2 \|\mathbf{w}_i \circ \mathcal{S}_i\|_1, \quad (36e)$$

where \mathcal{J}_1 and \mathcal{J}_2 are the corresponding Lagrangian multipliers, and α and β are positive scalars. The Eq. (36a) and Eq. (36b) perform the HSI spatial and spectral super-resolution, respectively, Eq. (36c) denotes the image reconstruction, and Eq. (36d) and (36e) represent the low-rank tensor approximation. Each subproblem has a closed-form solution. For Eq. (36a) and Eq. (36b), the subproblems can be solved by computing:

$$\mathcal{T}_{comp}(\mathcal{Q}) = \mathcal{T}_{sa}^T(\mathcal{Y}) + \beta \mathcal{X} + \mathcal{J}_1, \quad (37)$$

$$\mathcal{G} \times_3 (\mathbf{P}^T \mathbf{P} + \gamma \mathbf{I}) = \mathcal{Z} \times_3 \mathbf{P}^T + \gamma \mathcal{X} + \mathcal{J}_2, \quad (38)$$

where $\mathcal{T}_{comp} = \mathcal{T}_{sa}^T \mathcal{T}_{sa} + \beta \mathcal{I}$ is the composite operator on \mathcal{Q} , and $\mathcal{T}_{sa}^T(\mathcal{Y})$ means the transposed blurring and downsampling on \mathcal{Y} . Since it is hard for us to calculate the Eq. (37) and Eq. (38) directly, in our implementation, we unfold the 3-D tensors along the mode-3 to the 2-D matrixes as [5]. The solution of \mathcal{X} in Eq. (36c) can be calculated similar to that of Eq. (25), and the low-rank tensors $\hat{\mathcal{S}}_i$ can be updated by Eq. (10). Finally, the Lagrangian multipliers and penalization parameter are updated as follows:

$$\begin{cases} \mathcal{J}_1^{k+1} = \mathcal{J}_1^k + \beta (\mathcal{X} - \mathcal{Q}^{k+1}) \\ \mathcal{J}_2^{k+1} = \mathcal{J}_2^k + \gamma (\mathcal{X} - \mathcal{G}^{k+1}) \\ \beta^{k+1} = \delta \cdot \beta^k, \gamma^{k+1} = \delta \cdot \gamma^k. \end{cases} \quad (39)$$

The overall procedure is summarized in **Algorithm 4**.

V. EXPERIMENTAL RESULTS

A. Experimental Setting

Benchmark Datasets. We test three HSIs datasets:

- Columbia Multispectral database (CAVE)¹. The whole dataset consisting of 32 noiseless hyperspectral images of size $512 \times 512 \times 31$ are captured with the wavelengths in the range of 400-700 nm at an interval of 10 nm.
- Harvard hyperspectral datasets (HHD) [76]. The whole dataset consisting of 50 noisy hyperspectral images of size $1040 \times 1392 \times 31$ are captured with the wavelengths in the range of 420-720 nm at an interval of 10 nm.
- Remotely Sensed HSIs. Remotely sensed hyperspectral datasets are also used, i.e. Salinas.

Pre-processing. First, before the restoration process, all the original images were coded to an 8-bit scale for display convenience and uniform parameter setting. Second, for the non-local similarity cubic matching, we do not directly search from the 3-D cubics in the noisy data. Instead, for reducing computational load and matching accuracy, we proposed to average each band of the cubic, which can be regarded as a uniform filtering procedure, so that we can obtain a quite clean 2-D matrix. Note that, the non-local similarity matching processing is performing on this 2-D matrix, while our restoration is still processing on the whole 3-D cubics.

Baselines. For the HSI denoising methods, we compare with block-matching and 3D filtering (BM3D) [77], parallel factor analysis (PARAFAC) [21], low-rank tensor approximation (LRTA) [78], low-rank matrix recovery (LRMR) [10], adaptive non-local means denoising (ANLM) [79], nonnegative matrix factorization (NMF) [80], block-matching and 4D filtering (BM4D) [39], tensor dictionary learning (TDL) [23], intrinsic tensor sparsity regularization (ITSReg) [25], hyper-laplacian regularized low-rank tensor (LLRT) [27], and total variation regularized low-rank tensor decomposition (LRTDTV) [50]; for HSI deblurring, the competing methods include single image based hyper-Laplacian (HL) [81], and HSI deblurring methods fast positive deconvolution (FPD) [55] and spectral-spatial total variation (SSTV) [56]; for HSI super-resolution, we compare with coupled nonnegative matrix factorization (CNMF) [61], non-negative structured sparse representation (NSSR) [5] and non-local sparse tensor factorization (NLSTF) [32].

We use the codes provided by the authors or downloaded from their homepages, and fine-tune the parameters by default or follow the rules in their papers to achieve the best performance. And the Matlab code of our methods can be downloaded from the homepage of the author². For parameter settings of our method, the most important parameter is the number of non-local cubics, which is set between [100, 200] in correspondence with the noise level, respectively. The patch size is between [6, 8]. And another important factor is the regularization parameter η for HSI deblurring and super-resolution, which is set as 10^{-8} and 10^{-5} , respectively.

Evaluation Indexes. Four quantitative quality indexes are employed [23], including peak signal-to-noise ratio (PSNR),

TABLE II: Quantitative results of the competing methods under different blur levels on CAVE dataset.

Methods	HL	FPD	SSTV	DB-WLRTR
Gaussian (8*8, Sigma = 3)				
PSNR	37.28	38.84	37.61	55.68
SSIM	0.9460	0.9617	0.9527	0.9979
ERGAS	83.88	68.48	80.91	9.9635
SAM	0.0676	0.0734	0.0658	0.0250
Gaussian (17*17, Sigma = 7)				
PSNR	32.59	33.16	33.08	49.42
SSIM	0.8819	0.9114	0.8944	0.9926
ERGAS	137.14	125.11	129.84	20.87
SAM	0.1075	0.1163	0.0989	0.0439

structure similarity (SSIM), erreur relative globale adimensionnelle de synthese (ERGAS) and spectral angle map (SAM). The PSNR and SSIM evaluate the spatial quality, and the ERGAS and SAM assess the spectral quality. The larger PSNR and SSIM values are, the smaller ERGAS and SAM values are, the better the restored images are.

B. HSI Denoising

To visually illustrate the denoising performance of WLRTR, we choose two images *toy* of band 510nm under noise level $\sigma^2 = 30$, as shown in Fig. 6. In Fig. 6 (the green demarcated window), we can clearly see from the enlarged region that the proposed method has obtained clearer results, compared with other competing methods. Moreover, looking at the red demarcated window in Fig. 6, the proposed WLRTR is capable of well reconstructing the tiny hair texture. We also test the proposed WLRTR method on real noisy HSI. Since the noise level is unknown for real noisy images, we adopted an estimation method from [82] to estimate the noise level beforehand. In Fig. 7, from the demarcated window, we can observe that WLRTR method obtains smoother image with clearer texture and line pattern. In summary, WLRTR has obtained better performance in terms of noise suppression, detail preserving, artifacts-free, visual pleasure and PSNR value under different noise levels.

TABLE III: Quantitative results of the competing methods under different downsampling cases on CAVE dataset.

Methods	CNMF	NLSTF	NSSR	SR-WLRTR
Gaussian ($s = 8, 8*8, \text{Sigma} = 3$)				
PSNR	46.15	44.56	46.99	47.39
SSIM	0.9901	0.9816	0.9921	0.9931
ERGAS	35.15	41.89	30.21	29.26
SAM	0.0591	0.0961	0.0528	0.0500
Uniform ($s = 8$)				
PSNR	46.49	45.00	47.51	47.57
SSIM	0.9909	0.9847	0.9931	0.9934
ERGAS	34.56	39.06	28.84	28.82
SAM	0.0568	0.0869	0.0512	0.0493

We also present the overall quantitative assessments of all competing methods on CAVE in Table I. The highest PSNR and SSIM values and lowest ERGAS and SAM values are highlighted in bold. We have following observations. First, WLRTR consistently achieves the best performance in four assessments, which highly demonstrate the effectiveness of WLRTR for HSIs. Second, for random noise in CAVE, with the increase of noise level, the advantage of our method over other methods becomes more obvious. We can observe that the proposed method almost exceeds 4.3dB than BM4D at $\sigma^2 = 100$. Furthermore, we plot the PSNR values of each band of one single image *toy* in CAVE as an example, as shown in Fig. 8. It can be observed that the PSNR values of all the bands obtained by WLRTR are significantly higher than those of the other methods.

C. HSI Deblurring

There are relative fewer researches paying attention to HSI deblurring. We compare the proposed DB-WLRTR method with single image-based deblurring method hyper-Laplacian (HL) [81], and two HSI deblurring methods FPD [55] and SSTV [56]. The CAVE dataset is used for the comparison study. The Gaussian blur kernels with different sizes and standard deviations are tested. We assume the point spread function is known. From Table II, we can see that the proposed DB-WLRTR has an overwhelming advantage over the other methods under different Gaussian blur levels. The visual comparisons of the deblurring methods are shown in Fig. 9, from which we can see that the DB-WLRTR method produces much cleaner and sharper image edges and textures than other methods. It is noteworthy that the lost details, such as the text and the artificial flower, can be well recovered by our method.

D. HSI Super-resolution

We also test the proposed SR-WLRTR model on HSI super-resolution. The CAVE dataset is used for the comparison study. Both the Gaussian and uniform blur are tested with scaling factors $s = 8$. We compare the SR-WLRTR with the representative state-of-the-art methods, including both the matrix-based CNMF [61], NSSR [5] and tensor-based NLSTF [32]. The quantitative results are shown in Table III. It can be seen that the results of the proposed method are superior to

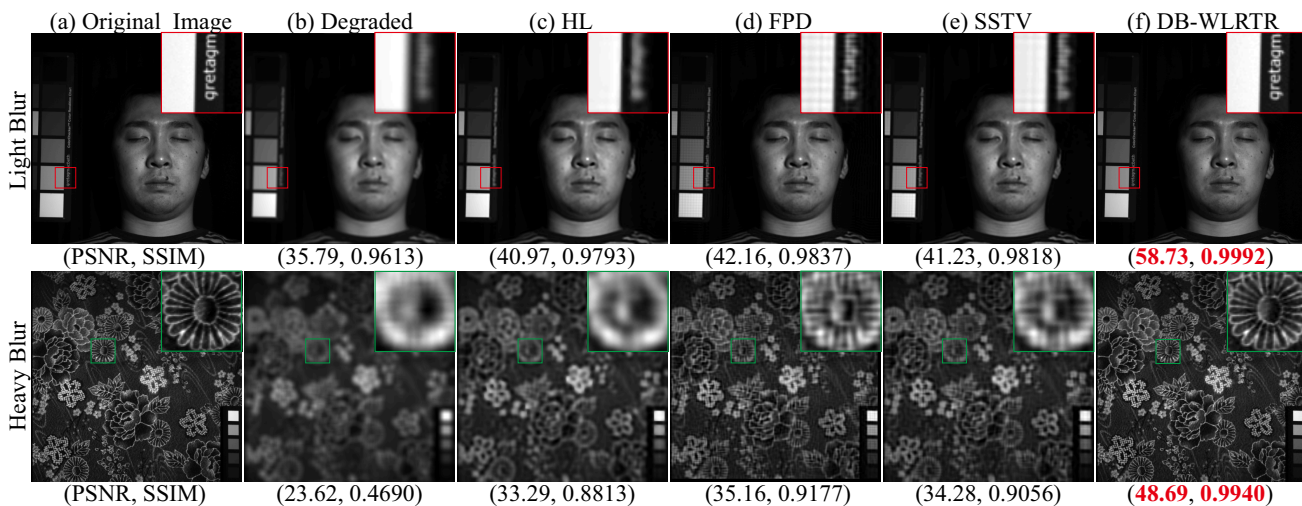

Fig. 9: Simulated deblurring results under different blur levels on CAVE dataset. The first row shows the light blur case (8×8 , Sigma = 3), and second row displays the heavy blur case (17×17 , Sigma = 7). (a) Original image at band 510 nm. (b) Degraded image, Deblurring results by (c) HL, (d) FPD, (e) SSTV, and (f) DB-WLRTR.

Fig. 10: Simulated SR results on CAVE dataset. The first row shows the SR results. The second row is the corresponding error map. From the first column to the last one is (a) Original image at band 700 nm, (b) Low-resolution image ($s = 8$, 8×8 , Sigma = 3), SR results by (c) CNMF, (d) NLSTF, (e) NSSR, and (f) SR-WLRTR.

the competing methods both the spatial and spectral aspects, especially the Gaussian blur. One visual comparison results at 700nm of the *flower* by all competing methods are shown in Fig. 10. All the competing methods can well recover the HR spatial structures of the scene, but the proposed method achieves the smallest reconstruction errors, especially for the sharp edges. In conclusion, compared with the matrix-based methods, the SR-WLRTR could better preserve the spatial-spectral structures with better recovering the spatial details and less spectral distortion; compared with the tensor-based methods NLSTF [32], the SR-WLRTR utilizes the low-rank tensor prior in HSI, thus resulting in better visual pleasing result, while there are obvious gridding artifacts in NLSTF.

E. HSI Destriping

In this section, we evaluate the WLRTR-RPCA model on the very common mixed noise in HSIs: random noise and stripe noise. We randomly added the stripe on HSI, and the locations of the stripes between the neighbor bands were different. It is worth noting that we do not know the location of the stripes. Figure 11 displays the noise removal results of the competing methods. It is obvious that there still exist some residual stripes in Fig. 11(c)-(j), which means these methods only work well for the random noise. In Fig. 11(l), the stripes are perfectly removed, and the detailed structure information in each image is well preserved without the introduction of any noticeable artifacts. The quantitative mixed noise removal results on both *Salinas* and *Cuprite* dataset are reported in Table IV. It is worth noting that the NMOg obtains

Fig. 11: Simulated mixed noise removal results under extremely heavy mixed random and stripe noise on *Cuprite* dataset. (a) Original image. (b) Noisy image. Denoising results by (c) BM3D, (d) PARAFAC, (e) LRMR, (f) ANLM, (g) NMF, (h) BM4D, (i) TDL, (j) ITSReg, (k) NMoG, and (l) WLRTR-RPCA.

TABLE IV: Quantitative results of the competing methods under mixed noises.

Method	Salinas(512*217*20)				Cuprite(200*200*89)			
	PSNR	SSIM	ERGAS	SAM	PSNR	SSIM	ERGAS	SAM
Noisy	21.57	0.2706	185.21	0.1787	18.84	0.3616	258.22	0.1798

PARAFAC	31.25	0.8220	66.52	0.0291	20.99	0.4110	178.00	0.1298
LRMR	35.28	0.8755	41.79	0.0276	21.63	0.5239	140.65	0.1157
ANLM	33.99	0.8704	42.40	0.0278	25.12	0.6259	102.21	0.0717
NMF	29.11	0.6781	35.30	0.0204	21.87	0.4383	165.51	0.1233
BM4D	36.18	0.9155	32.44	0.0198	21.66	0.4641	168.29	0.1255
TDL	38.80	0.9526	26.81	0.0117	21.52	0.4989	170.07	0.1271
ITSReg	33.32	0.8551	32.14	0.0234	21.45	0.4576	175.19	0.1313
NMoG	34.47	0.8773	38.64	0.0226	31.73	0.9178	120.54	0.1121
WLRTR-RPCA	39.38	0.9594	23.30	0.0104	33.42	0.9319	75.74	0.0581

a very competitive restoration result with higher quantitative value and better visual appearance. However, we can still observe the residual stripe and random noise in the result of NMoG. Moreover, the performance of NMoG heavily relies on the bands of the input HSI. Overall, the proposed method consistently obtains the best mixed noise removal results both quantitatively and qualitatively.

F. Analysis and Discussion

1) *Effectiveness of Reweight Strategy*: Here, we give a comprehensive comparison between LRTR model with/without the weighted strategy for different tasks, as shown in Table V. We can observe that both the baseline LRTR and WLRTR have significantly improved the restoration results. Moreover, the restoration results of the weighted LRTR are better than those of the LRTR, which validates the effectiveness of the weighted strategy in the tensor sparsity modeling.

2) *The Comparison of Each Scene*: We have reported the average results of all image scenes and all bands. For each scene in CAVE, we further compute the average PSNR value of all the competing methods under noise level $\sigma = 50$, as shown in Fig. 13. Indeed, the proposed WLRTR does not consistently outperform the LLRT for each image scene.

Fig. 12: Effects of the numbers of bands and non-local cubics.

Interestingly, we find that the LLRT performs better at the visually smoothed image scenes. However, for the image with abundant texture, such as the *cloth*, the proposed method works much better than that of the LLRT. This is reasonable since that the WLRTR mainly utilizes the self-similarity in the HSI from the global low-rank perspective, while the LLRT heavily relies on the local gradient smooth.

3) *Parameter Setting*: The number of bands B and non-local cubics K are two important parameters in the proposed method. In Fig. 12, we show the changes of the PSNR in CAVE with the different numbers of B and K , respectively. From Fig. 12(a), we can observe that the denoising results become gradually better with larger number of bands. It is worth noting that the curve still grows up slowly in the end. Normally, for a $512 \times 512 \times 31$ images, it would cost about 23 minutes with MATLAB 2017a, on an Intel i7 CPU at 3.6 GHz, and 32-GB memory.

From Fig. 12(b), we can observe that the denoising results become gradually better with larger number of bands. When the number of the band is smaller than 100, the PSNR value increases extremely fast. After the number of the band is larger than 100, the growing speed of the curve becomes relatively slow, and the PSNR value achieves its highest between 150

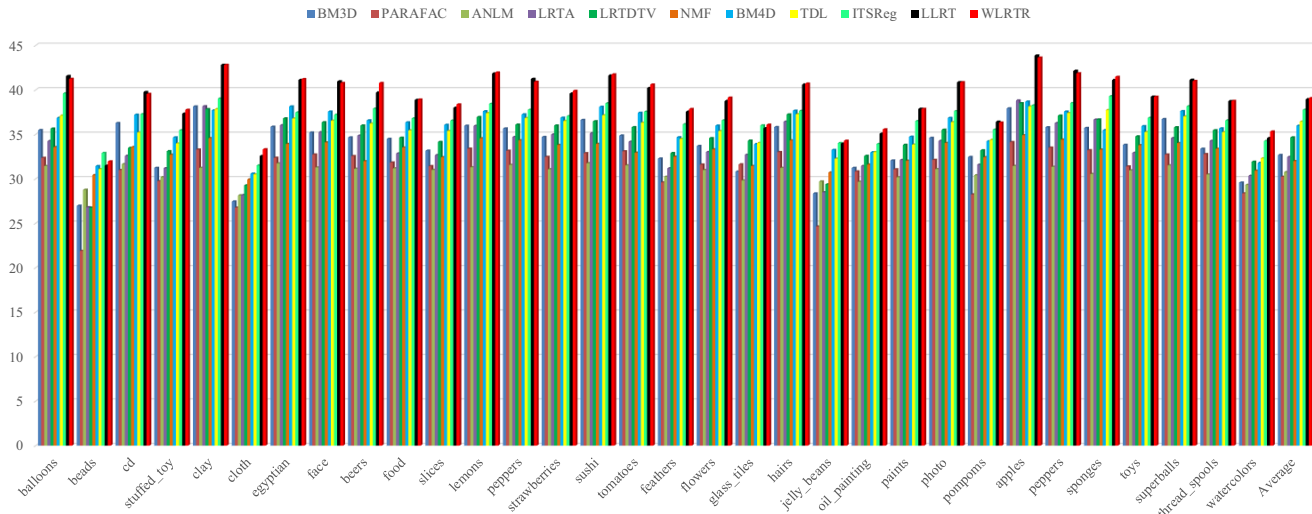

Fig. 13: Quantitative PSNR value comparison under noise level $\sigma^2 = 50$ on the dataset CAVE of each scene.

30	PSNR	18.58	28.22	29.69	29.87
	SSIM	0.3223	0.7854	0.8402	0.8444
40	PSNR	16.08	27.00	28.10	28.47
	SSIM	0.2388	0.7417	0.7872	0.7973

to 200. When the number of the band is larger than 230, the performance of WLRTR even deteriorates a little. We suppose it is due to the insufficient similarity between the target cubic and searching ones. Therefore, in our work, we set the number of non-local similarity cubics between 100 to 200.

4) *Extension to Multispectral Image:* Although WLRTR is proposed for HSIs which possess dozens or hundreds of continuous bands, it can be extended to multispectral images with fewer bands, such as RGB color image. Most of the previous color image processing methods usually handle the

RGB images in luminance space only or restore each channel separately, while ignoring the spectral correlation across the channel. On the contrary, the WLRTR jointly processes the R, G and B channel. We compared WLRTR with WNNM [72] which handles the color image in each channel, and color image denoising methods: LSCD [83] and CBM3D [84]. The PSNR and SSIM values on BSD are reported in Table VI. We can conclude that the joint utilization of RGB in color image really improves the denoising performance.

VI. CONCLUSION

In this paper, we have proposed a unified weighted low-rank tensor recovery method for HSIs restoration. The proposed WLRTR explicitly utilizes the spatial sparsity, non-local spatial-spectral cubic redundancy, and spectral consistency via higher-order low-rank property of each constructed 3-order tensor. We overcome the barriers of classical HSIs restoration methods that are not able to preserve the correlation of the spatial-spectral structure and can only be applied to one specific task. On one hand, we reveal the fact that tensor-based sparsity model indeed fits for the HSIs processing; on the other hand, thanks to the variable splitting methods, we show that various HSIs restoration problem can be unified in a framework, and transformed into several easier subproblems with closed-form solution. Further, for the low-rank tensor prior related subproblem, we introduce the weighted strategy to improve the restoration performance, in which the closed-form solutions have been analyzed. Besides, we consider the very common stripe noise in HSIs, utilize its structural and directional property, and extend WLRTR to the WLRTR-RPCA model.

Extensive simulated and real experiment results have been carried out against several state-of-the-art methods on various HSIs restoration tasks. The proposed methods have consistently outperformed state-of-the-art methods in both quantitative assessments and visual appearance, especially in HSI destriping, deblurring, and super-resolution domain, where few

tensor based methods have been proposed. In future, we would like to incorporate the learning-based tensor prior [85], [86] into the optimization model for better HSI restoration.
